Scientists have found that the rate of division in amoebas is controlled. Scientists believe that the transition from stage 2 to stage 3 is slowed by proteins. The additional time seems to help the amoeba change coding errors caused during DNA replication.

DNA can go through many processes to ensure that genes and traits are passed on to every cell in the body. When new cells are made, DNA must replicate itself in them. This ensures that the new cells are clones of the parent cells. Protein synthesis is another process that DNA does. These proteins determine which traits are made.

DNA Replication. Genes (the chemicals of heredity) are composed of DNA. Whenever new cells are made in either meiosis or mitosis, then new genes made of DNA are produced for the new cells. DNA Replication means the duplication of DNA that is identical to the original double-stranded DNA.; This replication of DNA must be exact, or a mutation of an incorrect sequence of nucleotides will occur.

Single-strand binding protein (SSB) is responsible for keeping the DNA unwound after the helicase. SSBs stabilize single-stranded DNA by binding to it. Next, you start making DNA that is complementary to the newly unwound/separated DNA. Note, all biological DNA synthesis occurs from the 5' to the 3' end.

DNA structure and function - MCAT Review

Extraction of DNA, RNA, and protein is the basic method used in molecular biology. These biomolecules can be isolated from any biological material for subsequent downstream processes, analytical, or preparative purposes. In the past, the process of extraction and purification of nucleic acids used to be complicated, time-consuming, labor-intensive, and limited in terms of overall throughput.

In translation, this RNA is then translated into proteins. Of course, the processes of transcription and translation are a little more complicated than that. Let's review the two processes: Transcription: DNA → RNA. Transcription is the first half of the Central Dogma. This is where DNA is translated into RNA.
